We report zero-field muon spin relaxation (μSR) measurements on $R\text{FeAsO}$ with $R=\text{La, Ce, Pr, and Sm}$. We study the interaction of the FeAs and R (rare-earth) electronic systems in the nonsuperconducting magnetically ordered parent compounds of $R\text{FeAsO}_{1-x}\text{F}_x$ superconductors via a detailed comparison of the local hyperfine fields at the muon site with available Mössbauer spectroscopy and neutron-scattering data. These studies provide microscopic evidence of long-range commensurate magnetic Fe order with the Fe moments not varying by more than 15% within the series $R\text{FeAsO}$ with $R=\text{La, Ce, Pr, and Sm}$. At low temperatures, long-range R magnetic order is also observed. Different combined Fe and R magnetic structures are proposed for all compounds using the muon site in the crystal structure obtained by electronic potential calculations. Our data point to a strong effect of R order on the iron subsystem in the case of different symmetry of Fe and R order parameters resulting in a Fe spin reorientation in the R -ordered phase in PrFeAsO . Our symmetry analysis proves the absence of collinear Fe- R Heisenberg interactions in $R\text{FeAsO}$. A strong Fe-Ce coupling due to non-Heisenberg anisotropic exchange is found in CeFeAsO which results in a large staggered Ce magnetization induced by the magnetically ordered Fe sublattice far above T_N^{Ce} . Finally, we argue that the magnetic R -Fe interaction is probably not crucial for the observed enhanced superconductivity in $R\text{FeAsO}_{1-x}\text{F}_x$ with a magnetic R ion.

Magnetic interaction between Fe and R subsystems

$$H_{ex}^{\text{Fe-R}} = \dots + J_0^{\text{Fe-R}} (\vec{F}^{\text{Fe}} \cdot \vec{F}^{\text{R}}) + J_1^{\text{Fe-R}} (\vec{I}_1^{\text{Fe}} \cdot \vec{L}_1^{\text{R}}) + \dots$$

$$H_{an-ex}^{\text{Fe-R}} = \dots + I_{3xz}^{\text{Fe-R}} (L_{3x}^{\text{Fe}} \cdot L_{3z}^{\text{R}}) + I_{3zx}^{\text{Fe-R}} (L_{3z}^{\text{Fe}} \cdot L_{3x}^{\text{R}}) + \dots$$

IR	Fe	R

(Submitted September 24, 2012; revised November 16, 2012)

Fiz. Nizk. Temp. **39**, 442–451 (April 2013)

Magnetic properties of a Ce^{3+} ion in two crystallographic phases of a nonsuperconducting oxypnictide $CeFeAsO$ were studied. Ce^{3+} -ion energy levels, g -factor values, temperature dependences of magnetic susceptibility components and the fourth-order anisotropy constant were calculated within a modified crystal field approach. It was shown that in the tetragonal and orthorhombic phases, the easy direction for the magnetic moment of Ce^{3+} ions corresponds to $[110]$ axis. Comparison of the calculated temperature dependences of susceptibility components to the respective experimental data showed that at temperatures below 100 K, it is necessary to take into account the internal field produced by the magnetic subsystem of iron ions. © 2013 AIP Publishing LLC

Objective of the work

Energy levels of the R^{3+} ions, g -factor values, temperature dependences of magnetic susceptibility components and *fourth*-order anisotropy constants have been calculated using the modified crystal field theory (MCFT).

The iron-subsystem effect on the magnetic properties of R^{3+} ions was theoretically studied for both crystallographic phases observed experimentally.

Magnetic anisotropy

Single-ion magnetic anisotropy

It is the result of joint interaction of the anisotropic crystal field and spin-orbit interaction.

Manifests itself in the form of an anisotropic dependence the magnetic moment from magnetic field direction

Anisotropy of exchange interaction of an ion pair

It is caused by the spin-orbit interaction between magnetic ions and ligands.

It manifests itself in terms of anisotropic interaction of an ion pair in the spin Hamiltonian.

Single-ion magnetic anisotropy

From the standpoint of the nature of the magnetic anisotropy all magnets are divided into two types

Magnets based on
3d-elements

Magnets based on
rare earth *4f*-elements

$$E_{SO} = \lambda (L \cdot S)$$

$$\begin{aligned} E_{SO} &\ll E_{CF} \\ \langle L \rangle &\approx 0 \\ M &= g_S \mu_B S \end{aligned}$$

$$\begin{aligned} E_{SO} &\gg E_{CF} \\ J &= L + S \\ M &= g_J \mu_B J \end{aligned}$$

Effective spin-Hamiltonian for the 3d-ion

Crystal Field Theory

$$H_{ee} \gg H_{CF} \gg H_{SO} \gg H_Z$$

$$\{Z_{eff}^{FI}, q_{eff}, \xi_{nl}\} = const$$

M. Pryce, 1950

$$H_{eff} = \langle \Gamma, \gamma | H_{SO} + H_Z | \Gamma, \gamma \rangle = 2\mu_B (\vec{H} \cdot \vec{S}) - \sum_{\Gamma', \gamma'} \frac{\left| \langle \Gamma', \gamma' | \mu_B (\vec{H} \cdot \vec{L}) + \lambda (\vec{L} \cdot \vec{S}) | \Gamma, \gamma \rangle \right|^2}{E_{\Gamma', \gamma'} - E_{\Gamma, \gamma}}$$

$$H_{eff} = \sum_{\mu, \nu} \left(\mu_B g_{\mu\nu} H_\mu S_\nu - \lambda^2 \Lambda_{\mu\nu} S_\mu S_\nu - \mu_B^2 \Lambda_{\mu\nu} H_\mu H_\nu \right)$$

$$g_{\mu\nu} = 2(\delta_{\mu\nu} - \lambda \Lambda_{\mu\nu}),$$

$$\mu, \nu = x, y, z$$

Single-ion anisotropy

$$\Lambda_{\mu\nu} = \sum_{\Gamma', \gamma'} \frac{\langle \Gamma, \gamma | L_\mu | \Gamma', \gamma' \rangle \langle \Gamma', \gamma' | L_\nu | \Gamma, \gamma \rangle}{E_{\Gamma', \gamma'} - E_{\Gamma, \gamma}}$$

Modified Crystal Field Approach (MCFA)

$$H = H_0 + V_{ee} + V_{CF} + V_{SO} + V_H$$

$$V = \sum_{i>j}^n \frac{e^2}{r_{ij}} + \sum_{k=1}^N \sum_{i=1}^n \frac{eq_k}{|\vec{r}_i - \vec{R}_k|} + \sum_{i=1}^n \xi(r_i) (\vec{l}_i, \vec{s}_i) + \mu_B \sum_{i=1}^n (\vec{l}_i + 2\vec{s}_i, \vec{H})$$

$$\|V_{\mu\nu} - \varepsilon\delta_{\mu\nu}\| = 0, \quad \mu, \nu = 1, \dots, C_{(2l+1)(2s+1)}^n$$

$$V_{\mu\nu} = \left\langle \Psi(\gamma S L M_S M_L) | V | \Psi(\gamma' S L' M_S M_L') \right\rangle$$

$$\Psi(SLJM_J) = \sum_{\mu} a_{\mu} \Phi_{\mu}(1, 2, \dots, n)$$

$$\psi(nlm_l m_s) = R_{nl}(r, \alpha) \cdot Y_{lm}(\vartheta, \varphi),$$

$$\alpha = Z_{eff} / n a_B$$

Calculation of g-factors and reconstruction of g-tensor components

$$g(\alpha, \beta, \gamma) = \frac{\Delta E}{\mu_B \Delta H(\alpha, \beta, \gamma)}$$

$$\vec{\xi} = (\cos \alpha, \cos \beta, \cos \gamma)$$

$$g_{(\alpha\beta\gamma)} = \frac{\vec{\mu} \cdot \vec{H}}{\mu_B \cdot |\vec{H}|} = \frac{\mu_B \cdot |\hat{g}\vec{J}| \cdot |\vec{H}|}{\mu_B \cdot |\vec{H}|} = |\hat{g}\vec{J}| = |\hat{g}\vec{\xi}^T|$$

g-factors and g-tensors calculated by MCFA and CFT

MCFA

g-tensors for the lowest doublet of Ce³⁺ in two phases

Cmma

$$\begin{bmatrix} 2.618 & 0 & 0 \\ 0 & 2.490 & 0 \\ 0 & 0 & 0.887 \end{bmatrix}$$

P4/nmm

$$\begin{bmatrix} 2.555 & 0 & 0 \\ 0 & 2.555 & 0 \\ 0 & 0 & 0.887 \end{bmatrix}$$

CFT P4/nmm

$$g_{\perp} = g_J \langle \psi_{(I)}^{\downarrow} | J^+ | \psi_{(I)}^{\uparrow} \rangle = 2,571;$$

$$g_{\parallel} = 2 g_J \langle \psi_{(I)}^{\uparrow} | J_z | \psi_{(I)}^{\uparrow} \rangle = 0,857.$$

Anisotropy of Kramers ion

To determine the anisotropy of the Kramers ion we should:

1. to measure (calculate) the g-factor values at least for 6 crystallographic directions;
2. to reconstruct the g-tensor components and to diagonalize the g-tensor;
3. the largest component of the diagonalized g-tensor together with the eigenvector of g-tensor indicate “easy direction” of the magnetic moment.

This direction is determined by the site crystallographic symmetry of paramagnetic ion.

The temperature dependence of the Ce^{3+} magnetic susceptibility

$$\chi_{\sigma\rho} = \frac{\mu_B^2}{k} \cdot \frac{C(T)}{T}$$

$$C_{\sigma\rho}(T) = \frac{\sum_{i=1}^N g_{(i)\sigma\rho}^2 \exp\left(-\frac{\varepsilon_{(i)\sigma\rho}}{kT}\right)}{\sum_{i=1}^N \exp\left(-\frac{\varepsilon_{(i)\sigma\rho}}{kT}\right)}$$

$$\mu_0 \cdot H_{ex} = 5 \text{ T}$$

- , □ - χ_x
- ▲, △ - χ_y
- , ○ - χ_z

Black symb. - $\mu_0 \cdot H_{int} = 0 \text{ T}$
 White symb. - $\mu_0 \cdot H_{int} \neq 0 \text{ T}$

Experimental and calculated dependences of magnetic susceptibility for CeFeAsO

— $\mu_0 \cdot H_{\text{ex}} = 1 \text{ T (exp.*)}$

— $\mu_0 \cdot H_{\text{ex}} = 5 \text{ T (exp.*)}$

--- $\mu_0 \cdot H_{\text{ex}} = 1 \text{ T (calc.)}$

--- $\mu_0 \cdot H_{\text{ex}} = 5 \text{ T (calc.)}$

*A. Jesche et al., *New Journal of Physics* **11** 10305 (2009).

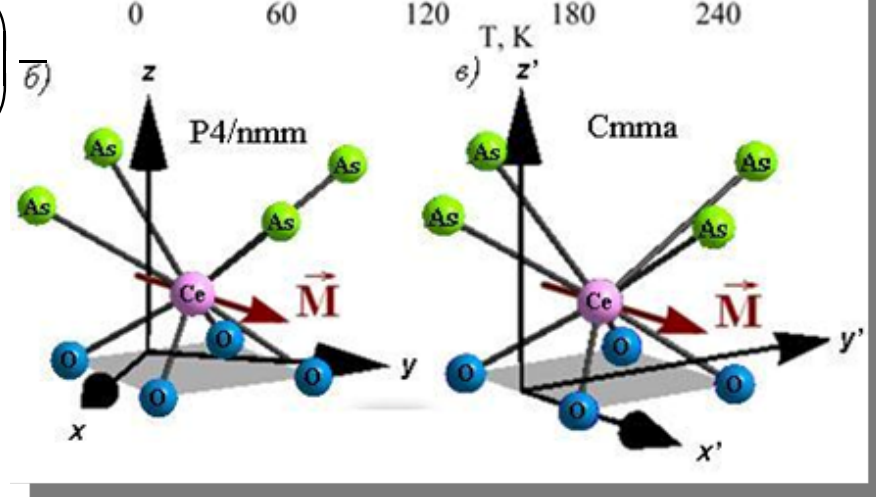

Fourth-order of anisotropy constant

$$F(h) = F_0(h^2) + \frac{1}{2g_J} (\chi_{\perp} - \chi_{\parallel}) \left(h_z^2 - \frac{1}{3} h^2 \right) - K_4 \cdot (h_x^4 + h_y^4 - 6h_x^2 h_y^2) + \dots$$

$$K_4 = (\gamma_4 - 2\alpha_4) / 8$$

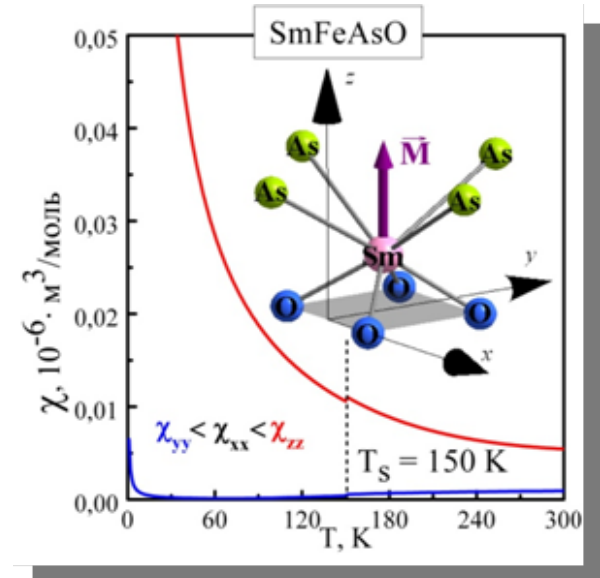

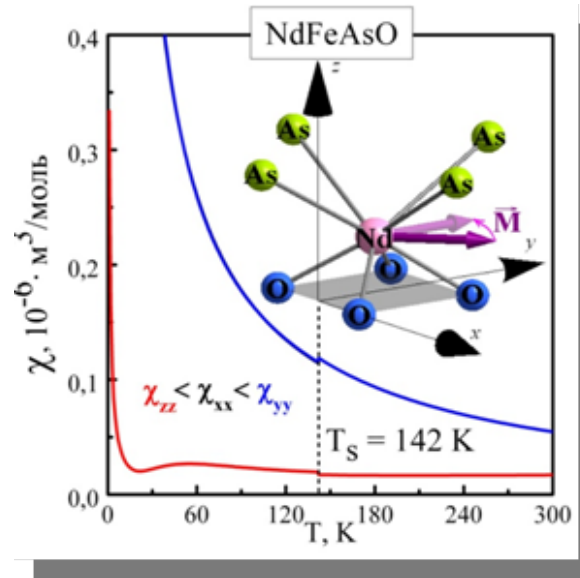

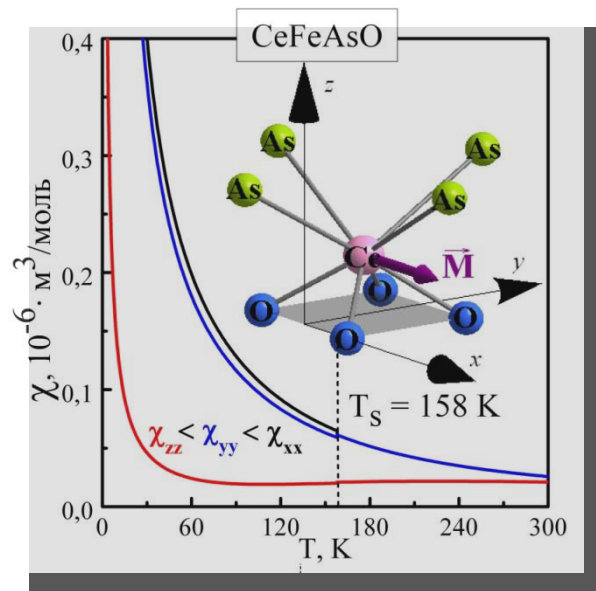

Magnetic moment direction in tetraphase coincides with one in orthophase!

<110>

<110>

Temperature dependence of R^{3+} susceptibility components

Ce³⁺: in the both phases the “easy direction” is [110] axis

Nd³⁺: in tetraphase the “easy direction” is [010] axis

in orthphase the “easy direction” is [110] axis

Sm³⁺: in the both phases the “easy direction” is [100] axis

Conclusions

- ▶ We propose new approach - modified crystal field theory - to calculate the magnetic properties of rare-earth ions. This approach allows to calculate the energy levels of 3d- and 4f-ions in arbitrary crystal environment with accounting of spin-orbit interaction.
- ▶ We show that the rare earth ions in the crystal-environment with 1111-symmetry always remain in highly anisotropic magnetic state.
- ▶ If this anisotropy is “easy plane” one than the R magnetic fluctuations always induce the Fe magnetic fluctuations, which are perpendicular to the plane
- ▶ One should stress that the iron magnetic subsystem has easy plane anisotropy. Accordingly, the easy plane Fe magnetic fluctuations will produce the rare-earth magnetic fluctuations along hard axis.
- ▶ We conclude that due to interplay between iron and rare earth subsystems in the R111 compounds the magnetic fluctuations of iron subsystems even in the doped nonmagnetic case never been isotropic.

Structural and magnetic transitions in CeFeAsO
